The **Church-Turing Thesis** implies that:

Turing machine algorithms Intuitive concept of algorithms =

- One of the most famous problems in CS.
- Given a list of cities and the distances between each pair of cities, what is the shortest possible route that visits each city and returns to the origin city?
- **NP-hard** problem! (This will be explained in a later elcture.)

Optimization problems

A decision problem has a *True* or *False* answer, whereas an "optimization" problem" involves finding an **extremum** of a function of several parameters.

Optimization Problems

Maximize or **minimize** a given function (over its *domain* of definition).

Algorithms and Heuristics

Optimization

problems

Useful strategies for tackling NP-hard problems

- Tractable special cases which can be solved quickly.
- 2 Exact methods
 - Exhaustive search.
 - Possibly better exponential time algorithms, e.g. Dynamic Programming.
- 3 Approximation methods fast, but not always correct.
 - Greedy search
 - Meta-heuristics

Exact Methods: Exhaustive search

- General problem-solving method
- Always finds solution if it exists
- Usually expensive tends to grow exponentially or worse

Exhaustive search

- 1: for for all possible candidates do
- 2: **if** candidate satisfies the problem's conditions **then**
- 3: **return** candidate
- 4: end if
- 5: end for
- 6: return no solution

Exact Methods: Dynamic Programming

- Build solution by first solving smaller problem instances
- Suitable when the problem has:
 - overlapping sub-problems
 - and optimal sub-structure making global optima a function of local optima.

Dynamic Programming

- 1: Charachterize structure of optimal solution.
- 2: Recursively define value of optimal solution.
- 3: Compute in a bottom-up manner store intermediate results in a table.

Algorithms Heuristics

Time-Space trade off

Dynamic Programming vs Exhaustive Search

- Exhaustive search tends to require less space but more time.
- Dynamic programming: space complexity can be big (table size).

Algorithms and Heuristics

Time-Space trade-off

Heuristic/Meta-heuristic methods

- Give up on exactness, but hope for near optimal solution, in "reasonable" time.
- May be the only feasible way to obtain near optimal solutions at relatively low computational cost.
- Two main approaches:
 - **1 Construction methods** work on partial solutions, trying to extend them in the best possible way to complete problem solutions.
 - **2** Local search methods move in the search space of complete solutions.

When is it best to use (meta-)heuristics to solve optimization problems? When the problem is NP-Hard, otherwise solve exactly.

Approximation methods: Greedy search

Build solution to a problem in an incremental way, starting with an empty initial solution and iteratively adding appropriate solution components (without backtracking) until a complete solution is built.

Algorithmic skeleton of the greedy construction heuristic

- 1: **s** ← empty solution
- 2: while s is not a complete solution do
- 3: *e* ← solution component with the best heuristic estimate
- 4: updates s by adding the component e
- 5: end while
- 6: return s

At each iteration, a component that maximizes the immediate gain is selected. (Decisions best in the short term without considering long term consequences)

It can be quite efficient.

Handbook of metaheuristics, p253:

In the simplest case, solution components are added in random order. Often better results are obtained if a heuristic estimate of the myopic benefit of adding solution components is taken into account. Greedy construction heuristics add at each step a solution component which achieves the maximal myopic benefit as measured by some heuristic information.

Solutions returned by greedy algorithms are typically of better quality than randomly generated solutions. Yet, a disadvantage of greedy construction heuristics is that they can generate only a very limited number of different solutions.

Additionally, greedy decisions in early stages of the construction process strongly constrain the available possibilities at later stages, often causing very poor moves in the final phases of the solution construction.

Meta-heuristics

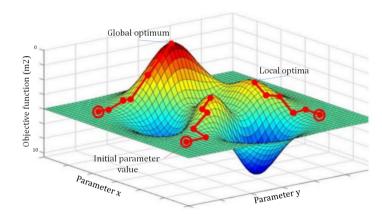

- Multi-starts
- **GRASP**
- Tabu Search
- Iterative improvement (Local search)
- Simulated annealing (Probabilities for worsening moves)
- Tabu search (Adaptive memory)
- Genetic Algorithms
- Ant Colony Optimization

Algorithms and Heuristics

Meta-houristics

Local Search - Neighbourhoods and Optima

Each solution candidate has a **neighbourhood** of solutions which can be reached by making small changes.

Local search may get stuck in a local optimum.

ACO

Local Search – Strategies

- **Best fit**: search the whole neighbourhood and then move to the best neighbour solution.
- First fit: search neighbourhood; move to the first improving solution found.
- Random first fit: pick random solutions from the neighbourhood; move to the first one found.
- Candidate list strategies: reduce the number of possible choices at each step: only search a subset of the neighbourhood solutions.
- Multi starts: restart every time the algorithm gets stuck (random changes, ruling out previous choices).

0) Iterative Improvement

- Search a "neighbourhood" of a solution for an improvement.
- Move to improved solution and search its neighbourhood.
- Keep going until you find no more improvements.

Can use with initial solution from greedy or randomly generated.

Try to minimize objective function *f* using local search

1: determine an initial candidate solution s.

▶ e.g. through greedy search

2: while s is not a local optimum do

3: choose a neighbour s' of s such that f(s') < f(s)

4: $s \leftarrow s'$

5: end while

6: return s

1) Greedy Randomized Adaptive Search Procedure (GRASP)

Algorithms and Heuristics

GRASP

1: **s** ← empty solution

2. while termination criterion is not satisfied do

generate candidate solution s' using a randomized greedy search 3.

perform a local search on s' 4:

if s' is better than s then $s \leftarrow s'$

6: end while

7: return s

2) Simulated Annealing

Effective approach modelled on the cooling of molten materials.

We have a variable *T* called temperature, which decreases, simulating cooling. Probabilities are based on the Boltzmann distribution.

- 1: determine initial candidate solution s
- 2: set initial temperature *T* according to annealing schedule
- 3: while termination condition not satisfied do
- 4: probabilistically choose a neighbour s' of s
- 5: **if** s' satisfies probabilistic acceptance criterion **then**
- 6: $s \leftarrow s'$
- 7: **end if**
- 8: update T according to annealing schedule
- 9: end while
- 10: return s

3) Tabu search

An alternative to the randomized approach is the memory-based approach

- Solutions consist of many components
- After removing a component from a solution, we mark it as tabu (forbidden) for some number of iterations
- The number of iterations is called the tabu tenure
- The neighbourhood is then restricted to use non-tabu components

- 1: determine initial candidate solution s
- while termination condition not satisfied do
- 3: determine set N of non-tabu neighbours of s
- 4: choose a best improving solution s' in N
- 5: update tabu attributes based on s'
- 6: end while
- 7: **return** s

4) Genetic Algorithms

So far we have looked at **trajectory approaches**, where we keep only one current solution and make progressive modifications to it.

Population based approaches use more than one solution at a time and make progressive changes to that population:

- Genetic/evolutionary algorithms
- Swarm intelligence (Ant Colony Optimisation, etc.)
- 1: determine initial population p
- 2: while termination criterion not satisfied do
- 3: generate set p_r of new candidates by **recombination**
- 4: generate set p_m of new candidates from p and p_r by **mutation**
- 5: select new population p from candidates in p, p_r , p_m
- 6: end while
